Module 7: Part II: Gibbs Sampling with an Application to Missing Data

Rebecca C. Steorts

Agenda

- ► Three stage Gibbs sampler
- ► Gibbs sampling (multi-stage sampler)
- ► Missing data (censoring) application

Multi-stage Gibbs sampler

Assume three random variables, with joint pmf or pdf: p(x, y, z)...

Set x, y, and z to some values (x_o, y_o, z_o) .

Sample x|y,z, then y|x,z, then z|x,y, and so on. More precisely,

- 0. Set (x_0, y_0, z_0) to some starting value.
- 1. Sample $x_1 \sim p(x|y_0, z_0)$. Sample $y_1 \sim p(y|x_1, z_0)$. Sample $z_1 \sim p(z|x_1, y_1)$.
- 2. Sample $x_2 \sim p(x|y_1, z_1)$. Sample $y_2 \sim p(y|x_2, z_1)$. Sample $z_2 \sim p(z|x_2, y_2)$. \vdots

Multi-stage Gibbs sampler

Assume d random variables, with joint pmf or pdf $p(v^1, \ldots, v^d)$.

At each iteration $(1, \ldots, M)$ of the algorithm, we sample from

$$v^{1} | v^{2}, v^{3}, \dots, v^{d}$$

 $v^{2} | v^{1}, v^{3}, \dots, v^{d}$
 \vdots
 $v^{d} | v^{1}, v^{2}, \dots, v^{d-1}$

always using the most recent values of all the other variables.

The conditional distribution of a variable given all of the others is referred to as the *full conditional* in this context, and for brevity denoted $v^i|\cdots$.

Example: Censored data

In many real-world data sets, some of the data is either missing altogether or is partially obscured.

One way in which data can be partially obscured is by *censoring*, which means that we know a data point lies in some particular interval, but we do not observe it.

Medical data censoring

Suppose 6 patients participate in a cancer trial, however, patients 1, 2 and 4 leave the trial early.

Then we know when they leave the study, but we don't know information about them as the trial continues.

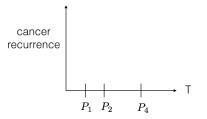

Figure 1: Example of censoring for medical data.

This is a certain type of missing data.

Heart Disease (Censoring) Example

- Researchers are studying the length of life (lifetime) following a particular medical intervention, such as a new surgical treatment for heart disease.
- ► The study consists of 12 patients.
- ► The number of years before death for each is

$$3.4, 2.9, 1.2+, 1.4, 3.2, 1.8, 4.6, 1.7+, 2.0+, 1.4+, 2.8, 0.6+$$

where the + indicates that the patient was alive after x years, but the researchers lost contact with the patient after that point in time.

Model

$$X_i = \begin{cases} Z_i & \text{if } Z_i \le c_i \\ c_i & \text{if } Z_i > c_i \end{cases} \tag{1}$$

$$Z_1, \dots, Z_n | \theta \stackrel{iid}{\sim} \mathsf{Gamma}(r, \theta)$$
 (2)

$$\theta \sim \mathsf{Gamma}(a, b)$$
 (3)

where a, b, and r are known.

- c_i is the censoring time for patient i, which is fixed, but known only if censoring occurs.
- ► X_i is the observation
 - ightharpoonup if the lifetime is less than c_i then we get to observe it $(X_i = Z_i)$,
 - ightharpoonup otherwise all we know is the lifetime is greater than c_i ($X_i = c_i$).
- θ is the parameter of interest—the rate parameter for the lifetime distribution.
- \triangleright Z_i is the lifetime for patient i, however, this is not directly observed.

Posterior inference

Goal: find $p(\theta, z_{1:n}|x_{1:n})$?

- 1. Straightforward approaches that are in closed form do not work (think about these on your own). Instead we turn to Gibbs!
- 2. To sample from $p(\theta, z_{1:n}|x_{1:n})$, we cycle through each of the full conditional distributions,

$$\theta \mid z_{1:n}, x_{1:n} \\ z_1 \mid \theta, z_{2:n}, x_{1:n} \\ z_2 \mid \theta, z_1, z_{3:n}, x_{1:n} \\ \vdots \\ z_n \mid \theta, z_{1:n-1}, x_{1:n}$$

sampling from each in turn, always conditioning on the most recent values of the other variables.

Likelihood

Recall the model is:

$$X_{i} = \begin{cases} Z_{i} & \text{if } Z_{i} \leq c_{i} \\ c_{i} & \text{if } Z_{i} > c_{i} \end{cases}$$
 (4)

$$Z_1, \ldots, Z_n | \theta \stackrel{iid}{\sim} \mathsf{Gamma}(r, \theta)$$
 (5)

$$\theta \sim \mathsf{Gamma}(a, b)$$
 (6)

The pdf associated with this random variable is rather strange, as it consists of two point masses: one at Z_i and one at c_i . The formula is

$$p(x_i|z_i) = \mathbf{1}(x_i = z_i)\mathbf{1}(z_i \le c_i) + \mathbf{1}(x_i = c_i)\mathbf{1}(z_i > c_i).$$

.

Full conditionals

The full conditionals are easy to calculate. Let's start with $\theta | \cdots$

Since $\theta \perp x_{1:n} \mid z_{1:n}$ (i.e., θ is conditionally independent of $x_{1:n}$ given $z_{1:n}$),

$$p(\theta|\cdots) = p(\theta|z_{1:n}, x_{1:n}) = p(\theta|z_{1:n})$$
(7)

= Gamma
$$(\theta \mid a + nr, b + \sum_{i=1}^{n} z_i)$$
 (8)

using the fact that the prior on θ is conjugate.

Full conditionals

Now we can easily find the full conditionals.

- Note that z_i is conditionally independent of z_i given θ for $i \neq j$.
- ▶ This implies that x_i is conditionally independent of x_j given z_i for $i \neq j$.

Now we have

$$p(z_i|z_{-i}, x_{1:n}, \theta) = p(z_i|x_i, \theta)$$

$$\underset{z_i}{\propto} p(z_i, x_i, \theta)$$

$$= p(\theta)p(z_i|\theta)p(x_i|z_i, \theta)$$

$$\underset{z_i}{\propto} p(z_i|\theta)p(x_i|z_i, \theta)$$

$$= p(z_i|\theta)p(x_i|z_i).$$

Full conditionals (continued)

There are now two cases to consider.

- 1. If $x_i \neq c_i$, then $p(z_i|\theta)p(x_i|z_i)$ is only non-zero when $z_i = x_i$.
- ▶ The density devolves to a point mass at x_i .
- 2. If $x_i = c_i$, then the density becomes $p(x_i|z_i) = \mathbf{1}(z_i > c_i)$, so

$$p(z_i|\ldots) \propto p(z_i|\theta)\mathbf{1}(z_i>c_i),$$

which is a truncated Gamma.

Sampling from the truncated Gamma

We sample from the truncated gamma using a modified version of the inverse CDF method.

For the censored values of Z_i we know c_i .

If we know θ (which we will in a Gibbs' sampler), we know the distribution of $Z_i|\theta \sim Gamma(r,\theta)$.

Let *F* be the CDF of this distribution.

Suppose we truncate this distribution to (c,∞) . The new CDF is

$$Y = P(Z_i < z) = \frac{F(z) - F(c)}{1 - F(c)}.$$

Therefore Y is a sample from the truncated Gamma.

Remark: when we implement the GS, we do not sample the observed values. We impute the censored values using the method just outlined.

Application to censored data

```
knitr::opts_chunk$set(cache=TRUE)
# Samples from a truncated gamma with
# truncation (t, infty), shape a, and rate b
# Input: t,a,b
# Output: truncated Gamma(a,b)
sampleTrunGamma <- function(t, a, b){</pre>
  p0 <- pgamma(t, shape = a, rate = b)
  # Use the modification of the inverse CD method
  x \leftarrow runif(1, min = p0, max = 1)
  y <- qgamma(x, shape = a, rate = b)
  return(y)
```

Application to censored data (continued)

```
# Gibbs sampler
# z is the fully observe data
# c is censored data
# n.iter is number of iterations
# init.theta and init.miss are initial values for sampler
# r,a, and b are fixed parameters
# burnin is number of iterations to use as burnin
sampleGibbs <-
  function(z, c, n.iter, init.theta, init.miss, r, a, b, burnin = 1){
  z.sum \leftarrow sum(z); m \leftarrow length(c); n \leftarrow length(z) + m
  miss.vals <- init.miss
  res <- matrix(NA, nrow = n.iter, ncol = 1 + m)
  for (i in 1:n.iter){
    var.sum <- z.sum + sum(miss.vals)</pre>
    theta \leftarrow rgamma(1, shape = a + n*r, rate = b + var.sum)
    miss.vals <- sapply(c, function(x) {sampleTrunGamma(x, r, theta)})</pre>
    res[i,] <- c(theta, miss.vals)</pre>
  return(res[burnin:n.iter,])
```

Set parameter values

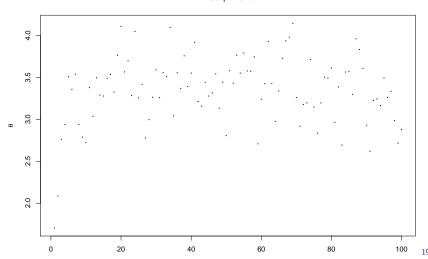

```
set.seed(5983)
# set parameter values and enter data
r < -10
a <- 1
b < -1
z \leftarrow c(3.4,2.9,1.4,3.2,1.8,4.6,2.8)
c \leftarrow c(1.2, 1.7, 2.0, 1.4, 0.6)
n.iter < -100
init.theta <- 1
init.missing <-</pre>
  rgamma(length(c), shape = r, rate = init.theta)
```

Run Gibbs sampler

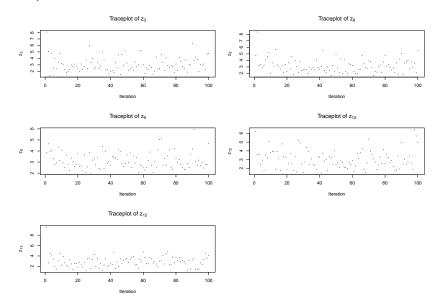

Let's first look at some diagnostics — trace plots and runnning average plots.

Traceplot of θ

Traceplot of θ

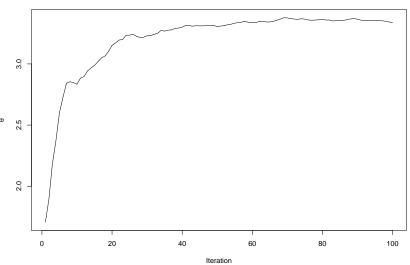

Traceplot of censored observations

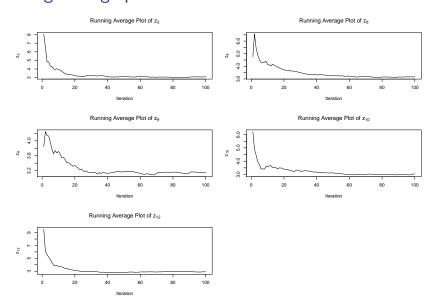

Running average plots

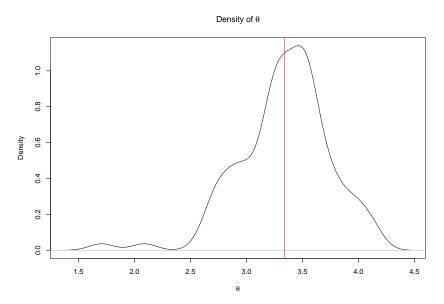

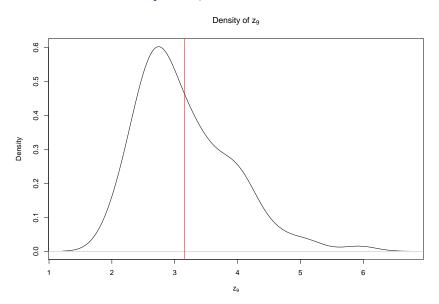

Running average plots

The estimated density of θ

The estimated density of z_9

Homework 8

Using the data and functions given to you (posted to Sakai with Homework 8), investigate the following questions:

- 1. Write code to produce traceplots and running average plots for the censored values for 200 iterations. Do these diagnostic plots suggest that you have run the sampler long enough? Explain.
- 2. Now run the chain for 10,000 iterations and update your diagnostic plots (traceplots and running average plots). Report your findings for both traceplots and the running average plots for θ and the censored values. Do these diagnostic plots suggest that you have run the sampler long enough? Explain.
- 3. Give plots of the estimated density of $\theta \mid \cdots$ and $z_9 \mid \cdots$. Be sure to give brief explanations of your results and findings. (Present plots for 10,000 iterations).
- 4. Finally, let's suppose that r = 10, a = 1, b = 100. Does your posterior change? What about when r = 10, a = 100, b = 1? (Use 10,000 iterations for the Gibbs sampler).
